How Surgeons Hide Donor Scars during Hair Transplant Surgery

When most people think of Hair Transplant, what comes to mind is usually basic information that's not particularly interesting or beneficial. But there's a lot more to Hair Transplant than just the basics.

Hair transplant procedures leave scars. It is just a fact of life. However, if the surgeries are handled in the proper manner, the scars are barely noticeable. They are thin to the point that they can barely be seen in most cases. Skilled doctors have ways of making the scars practically disappear.

First of all, the surgeon must be very skilled in choosing the site of the path where he harvests the donor tissue for the hair transplant. Its width should be no more than one centimeter in most instances. This allows the scalp to close completely when sutured back into place.

If the hair transplant procedure is done well, the scar will not be noticeable even if the patient likes to wear his hair in a short style. The scar will only become unsightly if the patient is genetically predisposed to keloid scarring. People who have this kind of problem need special treatment.

If a patient is known to suffer from keloid scarring, the first thing a reputable doctor will do before hair transplant surgery is to explain the possibility of unsightly scars. This requires a very honest surgeon, since the patient may decide the procedure is not worth the scarring it will cause.

It seems like new information is discovered about something every day. And the topic of Hair Transplant is no exception. Keep reading to get more fresh news about Hair Transplant.

The next step with such a patient would be to discuss ways the keloid could be covered. It could be camouflaged by wearing the hair just a little longer. Other patients have rubbery skin that stretches too much and so causes wide donor scars. These two groups add up to about 5% of the patients who have hair transplant surgery.

The other 95% of patients have no problems with their tiny scars at all. The hair transplant doctors are able to keep the donor strips very thin. They also use a double layer closure method to help the skin heal properly. As long as the surgeon knows what she is doing, the scars are a minor consideration.

Another aspect of scarring is when doctors go in for multiple hair transplant surgeries. A new strip of donor tissue has to be taken each time to supply the grafts for the new transplant. It would seem that this would lead to a large number of scars on the back and sides of the head.

Actually, there is a hair transplant procedure that keeps the scarring to one thin line. It consists of cutting the new thin donor strip immediately above the original scar. In most cases, the old scar is removed at the same time. When the wound is stitched up, the entire area of both the old scar and the new cut are sewn into one line. If multiple surgeries are done, this procedure is used every time.

Hair transplant surgery leaves scars. That much is certain. If you are one of the unlucky few who scar easily, you might have scars big enough that you have to hide them. Yet, if you are like most people, you will not have scars that anyone will notice at all.

When word gets around about your command of Hair Transplant facts, others who need to know about Hair Transplant will start to actively seek you out.
